THE SUMMER VISION PROJECT

Seymour Papert

The summer vision project is an attempt to use our summer workers effectively in the construction of a significant part of a visual system. The particular task was chosen partly because it can be segmented into sub-problems which will allow individuals to work independently and yet participate in the construction of a system complex enough to be a real landmark in the development of "pattern recognition".

Computer vision and “pattern recognition”

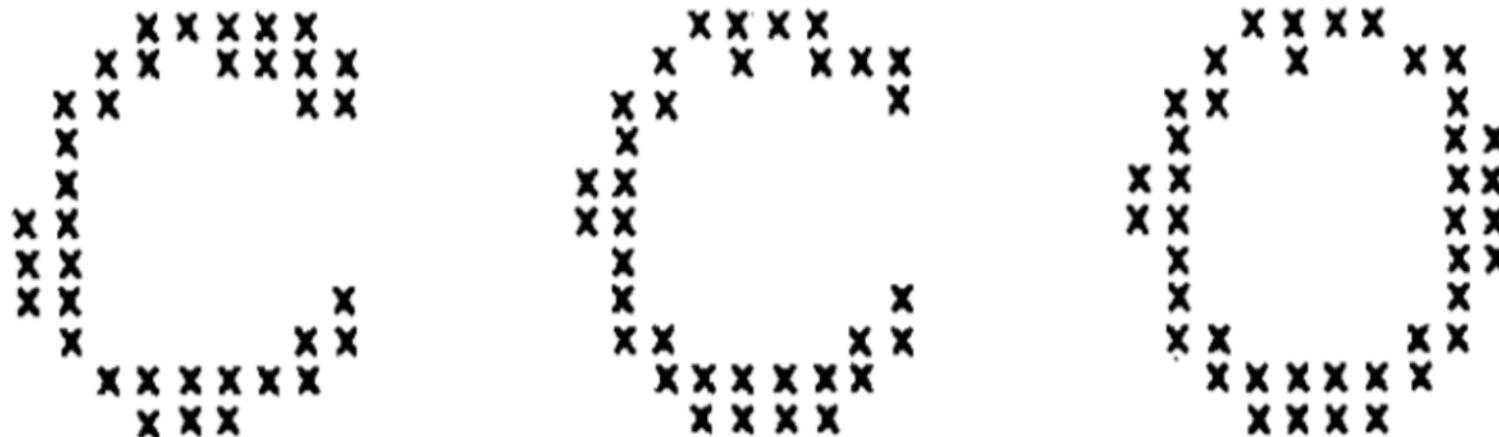

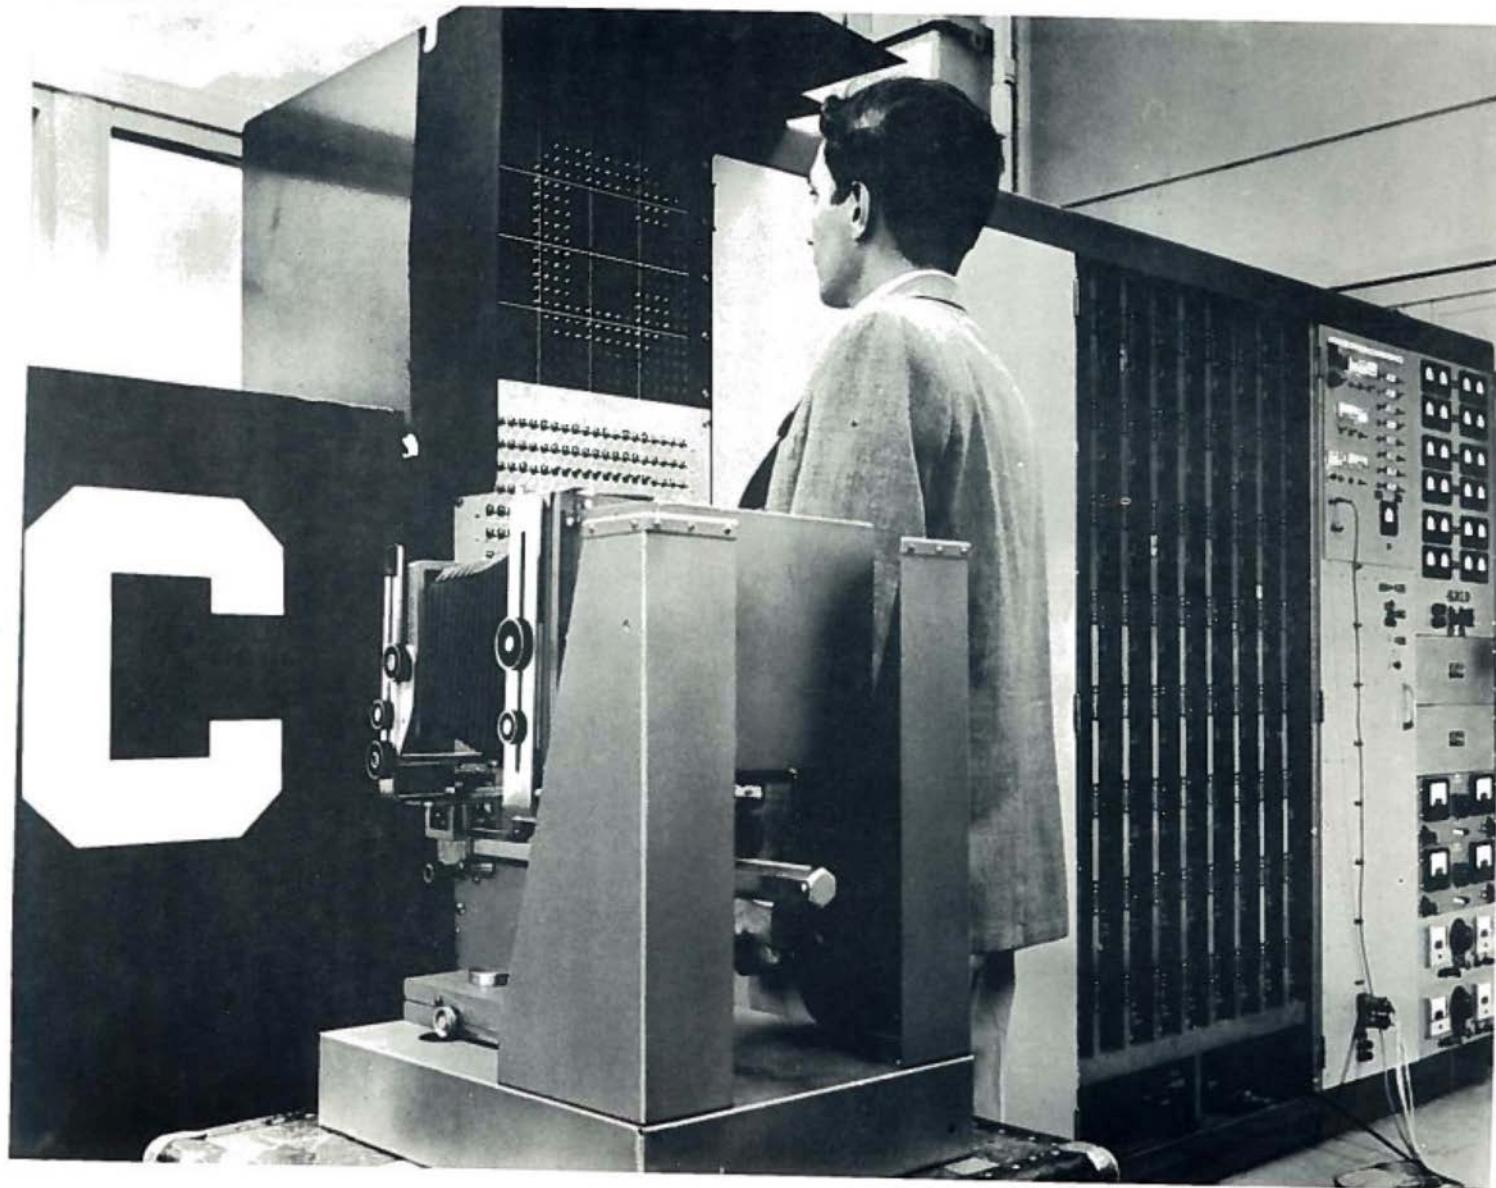

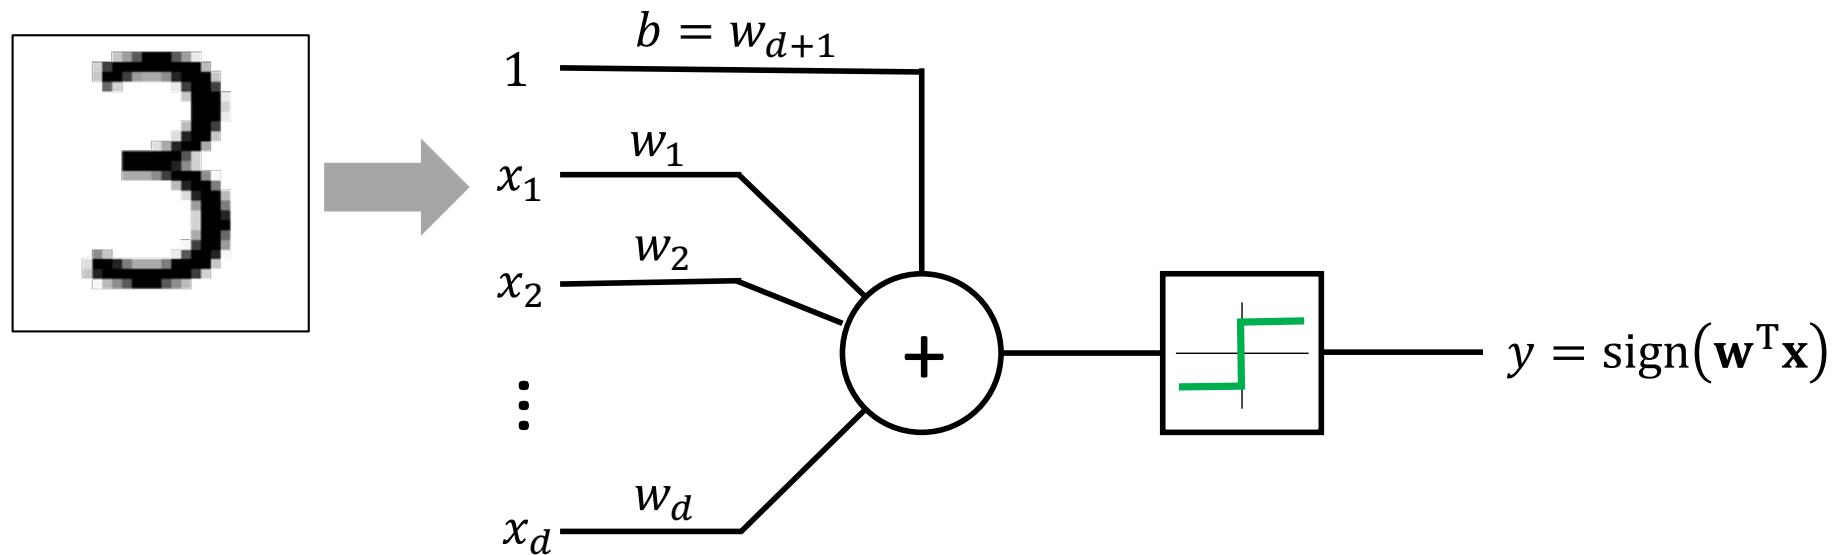

Fig. 4. Correlations in binary patterns. The center pattern, which may be considered the “unknown,” differs from each of the outside patterns (“templates”) by 9 bit positions. The effect of the correlations among the mismatch bits must thus be taken into account for correct identification. Although this is an artificially constructed example, instances of such neighborhood correlations frequently occur in practice.

Why neural networks failed in image analysis?

Local connectivity

Neurocognitron: key features

Neurocognitron: key features

“The response of [Perceptron and similar models...] was severely affected by the shift in position and/or by the distortion in shape of the input patterns. Hence, their ability for pattern recognition was not so high.”

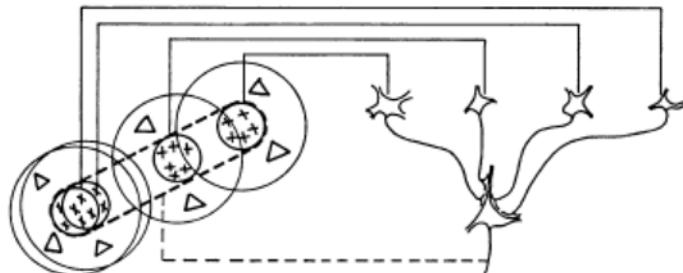

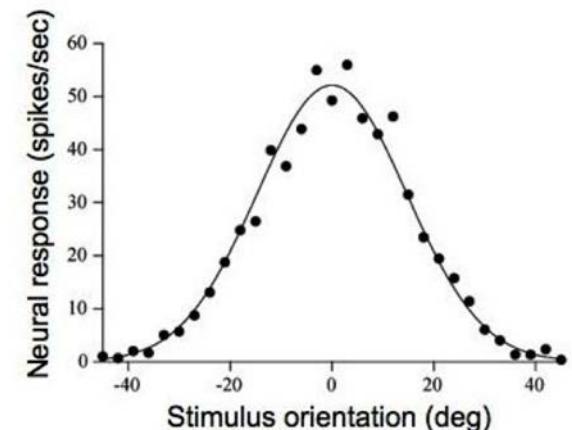

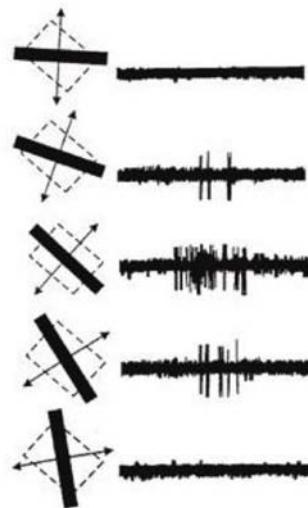

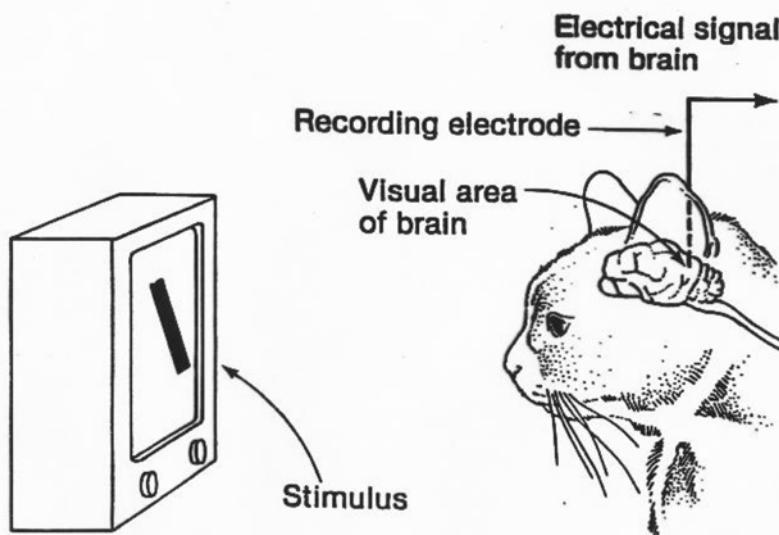

“The network is self-organized by "learning without a teacher", and acquires an ability to recognize stimulus patterns based on the geometrical similarity (Gestalt) of their shapes without affected by their positions.”

$$\varphi[x] = \begin{cases} x & x \geq 0 \\ 0 & x < 0 \end{cases}$$

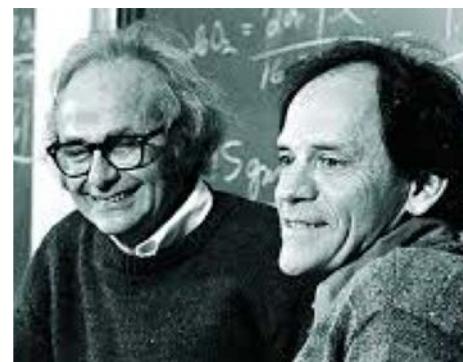

ReLU in 1980!

“The structure of this network has been suggested by that of the visual nervous system of the vertebrate”

Biological inspiration

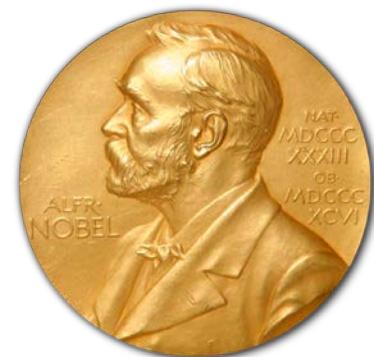

Text-fig. 19. Possible scheme for explaining the organization of simple receptive fields. A large number of lateral geniculate cells, of which four are illustrated in the upper right in the figure, have receptive fields with 'on' centres arranged along a straight line on the retina. All of these project upon a single cortical cell, and the synapses are supposed to be excitatory. The receptive field of the cortical cell will then have an elongated 'on' centre indicated by the interrupted lines in the receptive-field diagram to the left of the figure.

Key insights

- Trained with backpropagation
- Convolutional filters
- 5 layers
- Average pooling
- Sparse connections (to reduce complexity)
- tanh activation
- Dataset: MNIST (60K training images)

LeCun 1993

What's Hidden in the Hidden Layers?

*The contents can be easy to find with a geometrical problem,
but the hidden layers have yet to give up all their secrets*

David S. Touretzky and Dean A. Pomerleau

tions, we fed the network road images taken under a wide variety of viewing angles and lighting conditions. It would be impractical to try to collect thousands of real road images for such a data set. Instead, we developed a synthetic road-image generator that can create as many training examples as we need.

To train the network, 1200 simulated road images are presented 40 times each, while the weights are adjusted using the back-propagation learning algorithm. This takes about 30 minutes on Carnegie Mellon's Warp systolic-array supercomputer. (This machine was designed at Carnegie Mellon and is built by General Electric. It has a peak rate of 100 million floating-point operations per second and can compute weight adjustments for back-propagation networks at a rate of 20 million connections per second.)

Once it is trained, ALVINN can accurately drive the NAVLAB vehicle at about 3½ miles per hour along a path through a wooded area adjoining the Carnegie Mellon campus, under a variety of weather and lighting conditions. This speed is nearly twice as fast as that achieved by non-neural-network algorithms running on the same vehicle. Part of the reason for this is that the forward pass of a back-propagation network can be computed quickly. It takes about 200

milliseconds on the Sun-3/160 workstation installed on the NAVLAB.

The hidden-layer representations ALVINN develops are interesting. When trained on roads of a fixed width, the net-

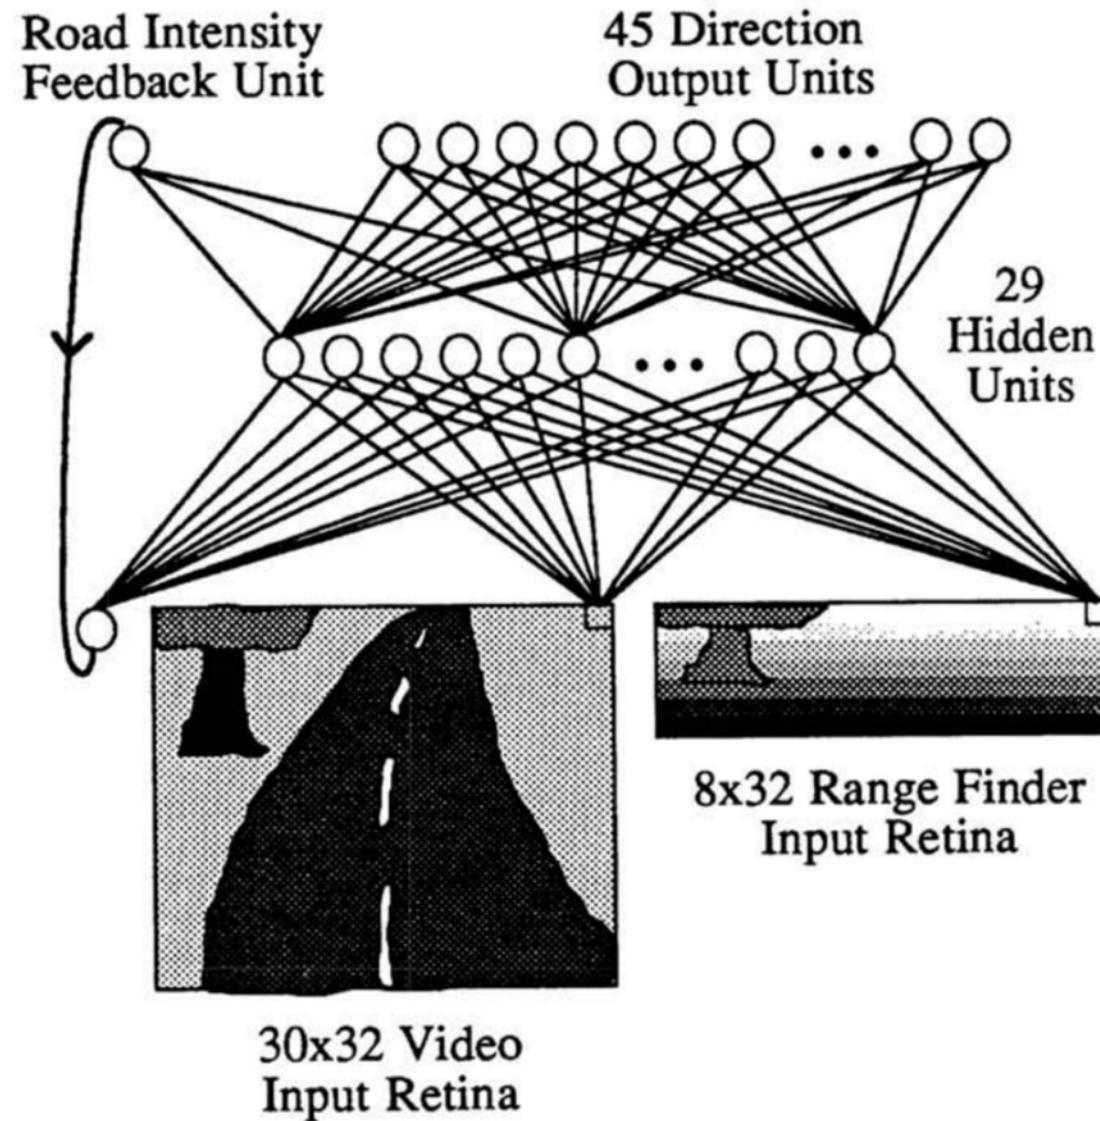

work chooses a representation in which hidden units act as detectors for complete roads at various positions and orientations. When trained on roads of variable

Key insights

- 11 layers
- Large convolutional filters 11x11
- Max pooling
- ReLU activation
- Dataset: ImageNet (1.2M training images)
- Data augmentation
- Trained on GPU (GTX 580, took 5-6 days!)

Key insights: ReLU

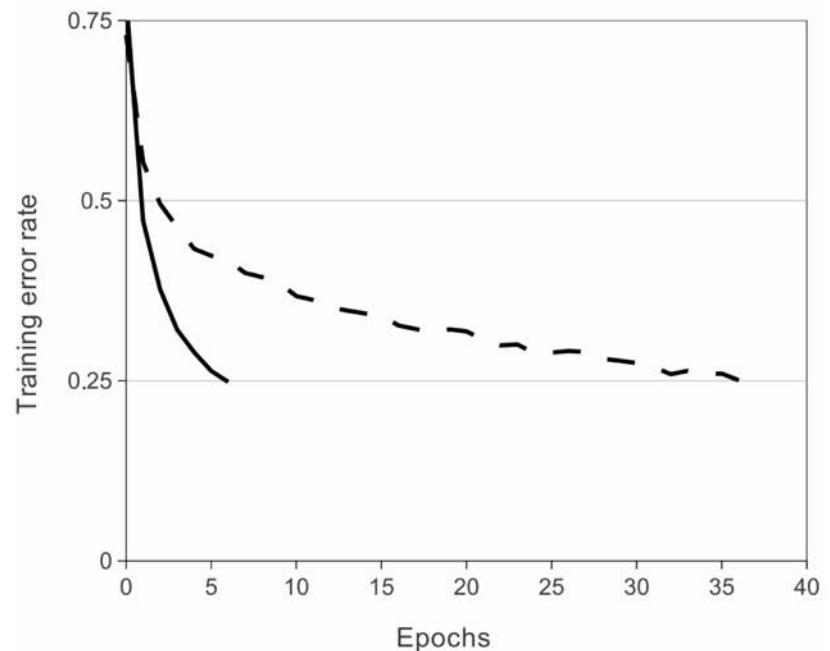

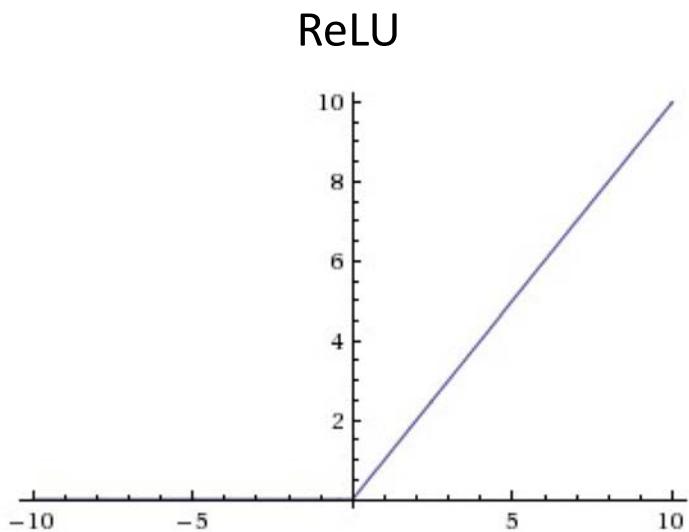

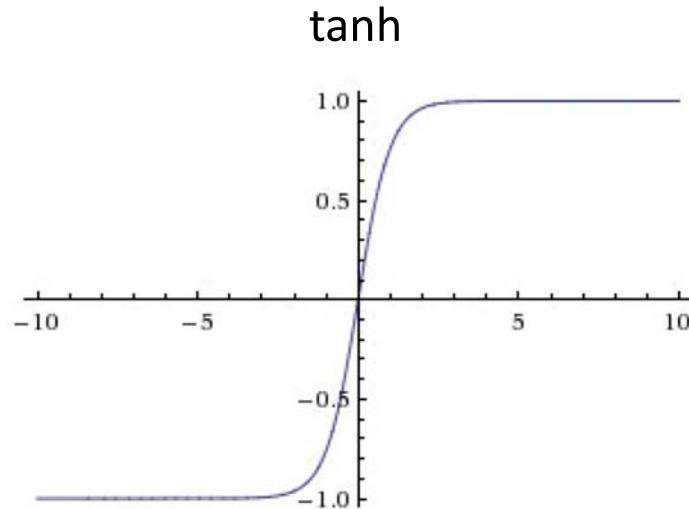

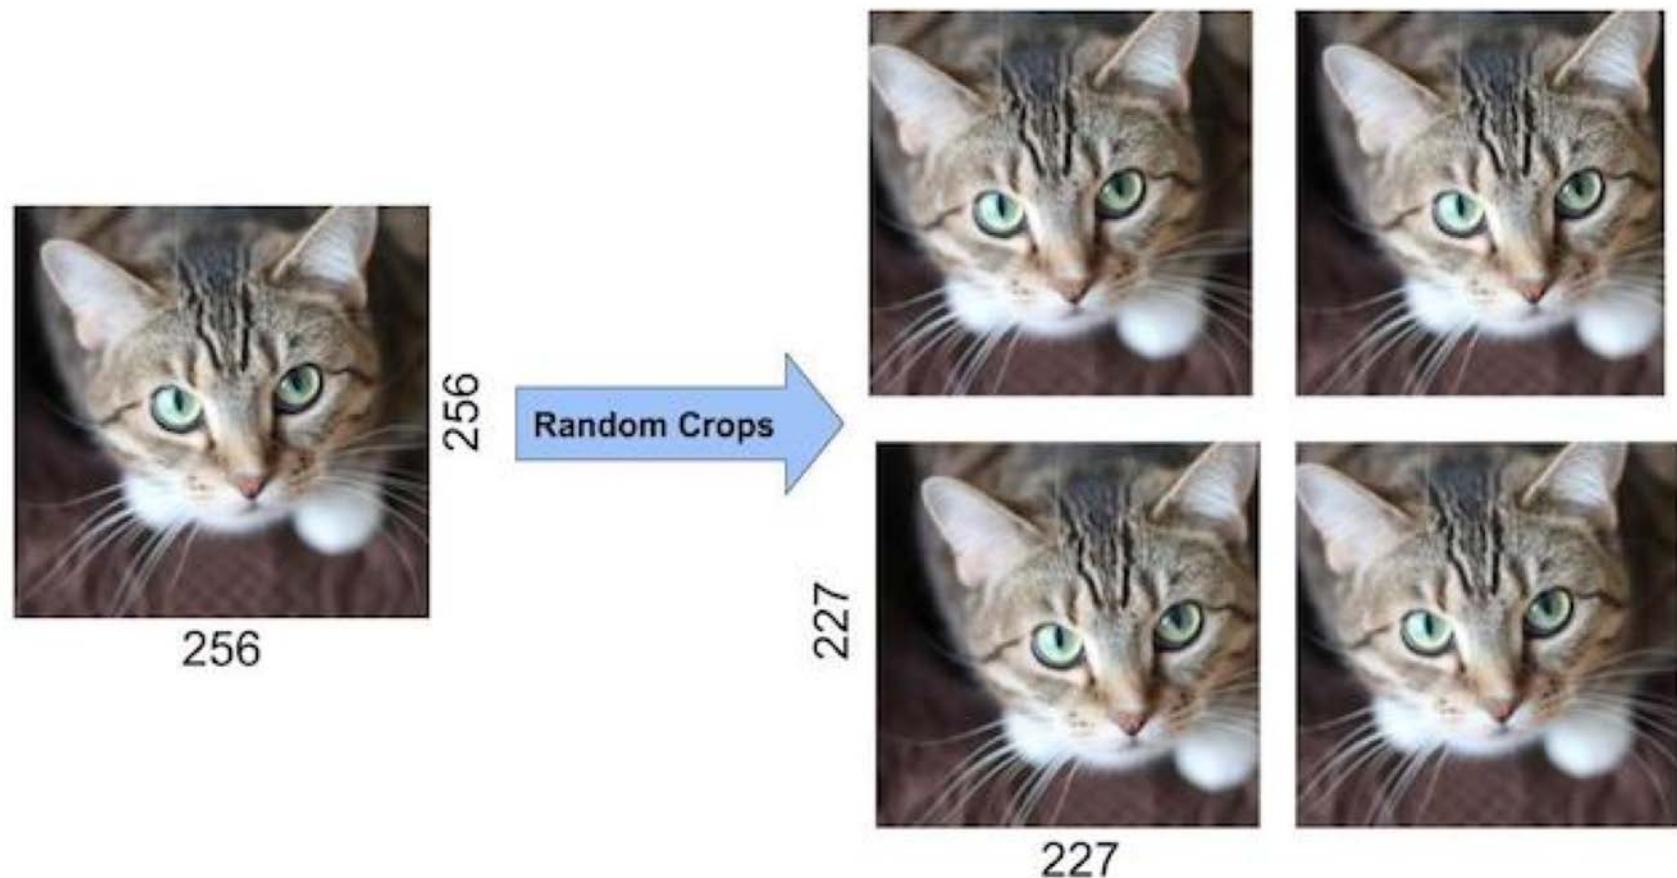

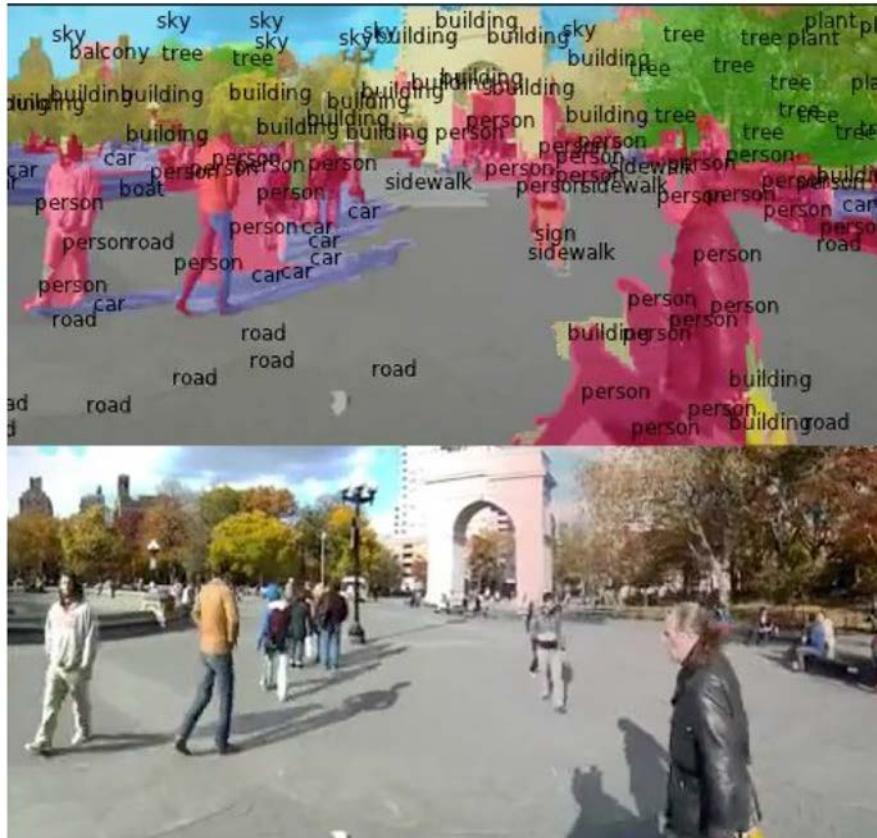

Figure 1: A four-layer convolutional neural network with ReLUs (**solid line**) reaches a 25% training error rate on CIFAR-10 six times faster than an equivalent network with tanh neurons (**dashed line**). The learning rates for each network were chosen independently to make training as fast as possible. No regularization of any kind was employed. The magnitude of the effect demonstrated here varies with network architecture, but networks with ReLUs consistently learn several times faster than equivalents with saturating neurons.

Key insights: data augmentation
